

View EXIF Data on Mac

In OS X, you can technically right-click on an image and choose **Get Info** to see some metadata about a picture:

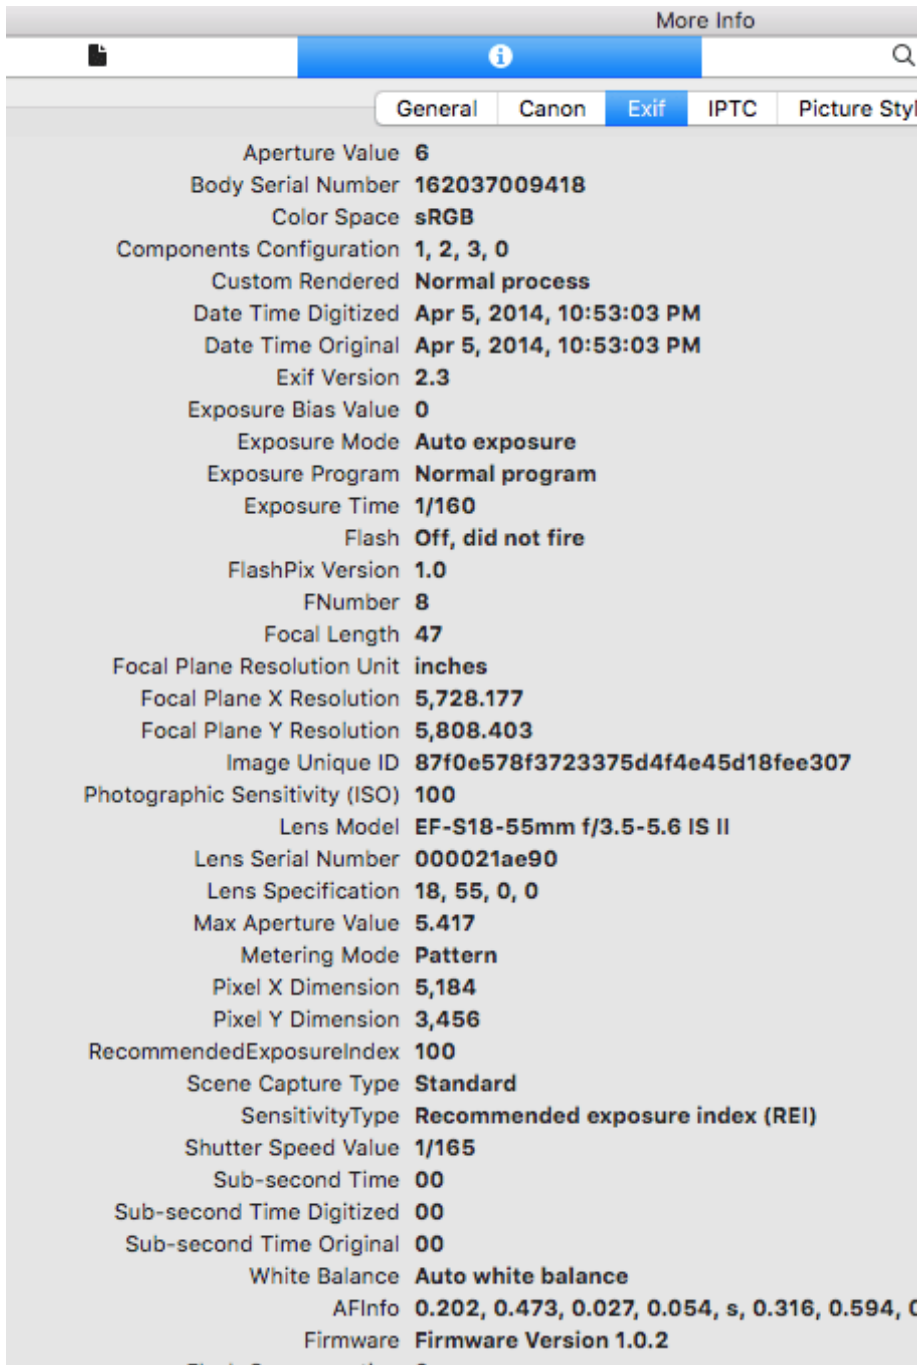

However, as you can see, this is not really a lot of information at all.. Luckily, there is one other way to view more detailed Exif data on the Mac and that is by using **Preview**. Just right-click on the photo and choose Open With – Preview.

In the toolbar menu, click on **Tools** and then **Show Inspector**.

In the Inspector window, click on the Exif tab and you should see all the Exif data for that picture. You'll see more or less depending on how much Exif data is stored in the image.

Note that with Preview, it'll even have a separate tab for the make of the camera, if there is enough info stored in the photo. Above, I have a Canon tab in addition that gives me more details about the exact camera and lens.
